Linear Time Series

Christian Francq

CREST-ENSAE

Chapter 3: Using ARMA and SARIMA Models

Outline

Preliminary transformations

Before fitting an ARMA model to a real time series, one has to check that stationarity is a plausible assumption.

Preliminary transformations are called for if the data exhibit visible deviations from stationarity (trend, seasonality...).

Ordinary and seasonal differentiations are used to suppress trends and seasonalities.

The logarithmic transformation, $Y_t = \log X_t$ for $X_t > 0$, may allow to reduce some nonlinearities (e.g. heteroskedasticity). For macroeconomic (financial) series, growth rates (log-returns) $Y_t = \log X_t / X_{t-1}$ are often used. More generally, one can use the Box-Cox transformation:

$$f_\lambda(X_t) = \begin{cases} (X_t^\lambda - 1)/\lambda, & X_t \geq 0, \ \lambda > 0 \ \text{ or } \ X_t > 0, \ \lambda \neq 0 \\ \log(X_t) & X_t > 0, \ \lambda = 0 \end{cases}$$

Different steps

ARMA(p, q):

$$X_t - \phi_1 X_{t-1} - \cdots - \phi_p X_{t-p} = \epsilon_t - \psi_1 \epsilon_{t-1} - \cdots - \psi_q \epsilon_{t-q} + c.$$

i) A priori identification of orders p and q (acf, pacf, ...);

ii) Estimation of the parameters (LS, ML);
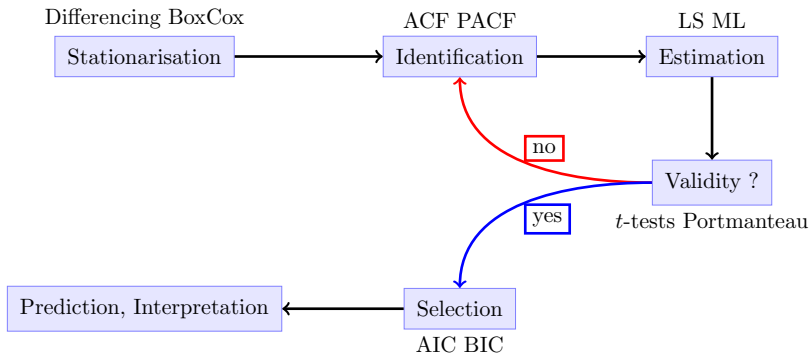

iii) Diagnostic checking

iv) Model choice (AIC, BIC...).

Seasonal ARIMA models

Ordinary differentiation

If no visible deviation from stationarity occurs and if the empirical autocorrelations decrease rapidly, an ARMA model can be fitted on the series after mean correction.

Otherwise we look for a transformation of the series achieving such properties. If the series exhibits a trend but no seasonality, differences can be used.

Differencing leads to consider the class of autoregressive-integrated moving average, or ARIMA models.

Definition

Let d a nonnegative integer. A series (X_t) is an ARIMA(p, d, q) if

$$Y_t = (1 - B)^d X_t$$

is a causal ARMA(p, q), possibly with a mean μ.

We thus have

$$\phi(B)(1 - B)^d X_t = \psi(B)\epsilon_t + c, \quad \epsilon_t \text{ WN } (0, \sigma^2)$$

where ϕ is a polynomial of degree p with all its roots of modulus > 1 and ψ is a polynomial of degree q.

(X_t) is stationary only if $d = 0$.

Remarks

If $d \geq 1$, any polynomial of degree $d-1$ can be added to X_t without changing the model.* In particular, ARIMA are thus appropriate for series with a trend.

ARIMA can also be appropriate for series without a deterministic trend (a random walk for instance).

Estimation of the parameters is thus based on the differenced series $(1-B)^d X_t$. Supplementary assumptions are required for prediction of the original series.

---

*By induction on d, check that $(1-B)^d (a_0 + a_1 t + \cdots + a_{d-1} t^{d-1}) = 0$

Prediction based on ARIMA models

Suppose that

$$(I - B)^d X_t = Y_t, \quad t \geq 1$$

where (Y_t) is a causal ARMA(p, q) and that the vector $(X_{1-d}, \ldots, X_0)$ is non correlated with $(Y_t, \quad t \geq 1)$. We thus have

$$X_t = Y_t - \sum_{j=1}^{d} \binom{d}{j} (-1)^j X_{t-j}, \quad t \geq 1.$$

It can be assumed that $(X_{1-d}, \ldots, X_n)$ are observed (and thus also $(Y_1, \ldots, Y_n)$). We then have

$$\hat{X}_{n+1|n} = \hat{Y}_{n+1|n} - \sum_{j=1}^{d} \binom{d}{j} (-1)^j X_{n+1-j}.$$

Seasonal ARIMA models | Monte Carlo experiments
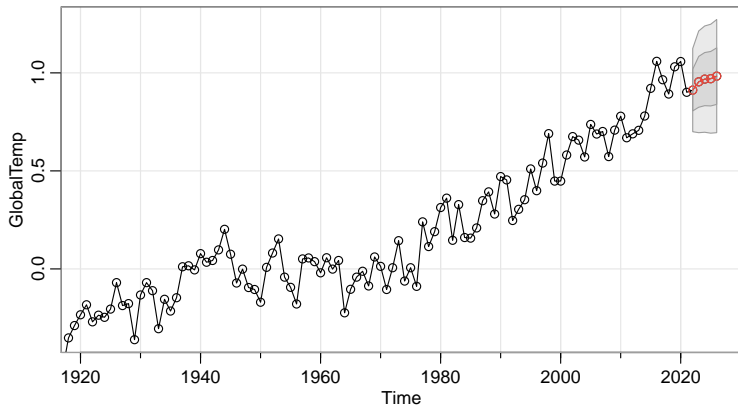

Non stationary seasonal series

Many monthly (Leisure employment) and quarterly series present strong seasonality, respectively of order $s = 12$ and $s = 4$.

Each date $t = ks + v$ correspond to a cycle/year k and a season/month $v \in \{1, \ldots, s\}$. If the distribution of X_t depends on s, the series (X_t) is not stationary.

A SARIMA model for the non-stationary series X_t is an ARMA model on the stationary series

$$Y_t = (1 - B)^d (1 - B^s)^D \sim ARMA.$$

For parsimony reasons, the AR and MA polynomials are generally product of polynomials in B and B^s.

Seasonal ARIMA models

SARIMA models allow to handle a random seasonal component.

Suppose that observations of a monthly time series are available over r years

<center>Month</center>

Year	1	2	...	12
1	X_1	X_2	...	X_{12}
2	X_{13}	X_{14}	...	X_{24}
⋮	⋮	⋮	⋮	⋮
r	$X_{1+12(r-1)}$	$X_{2+12(r-1)}$	...	$X_{12+12(r-1)}$

Box-Jenkins methodology | Definition of a SARIMA
Integrated ARMA models | Leisure employments in US
Seasonal ARIMA models | Monte Carlo experiments

Same ARMA model for each column

Each column is viewed as a series generated by the same ARMA(P,Q) model. For the jth month we have:

$$
\begin{aligned}
X_{j+12t} \;=\; & \phi_1 X_{j+12(t-1)} + \ldots + \phi_P X_{j+12(t-P)} \\
& + U_{j+12t} - \psi_1 U_{j+12(t-1)} + \ldots + \psi_Q U_{j+12(t-Q)}.
\end{aligned}
$$

We thus have

$$
\begin{aligned}
X_t \;=\; & \phi_1 X_{t-12} + \ldots + \phi_P X_{t-12P} \\
& + U_t - \psi_1 U_{t-12} + \ldots + \psi_Q U_{t-12Q},
\end{aligned}
$$

that is,

$$
\Phi(B^{12})X_t = \Psi(B^{12})U_t.
$$

Box-Jenkins methodology   **Definition of a SARIMA**
Integrated ARMA models   Leisure employments in US
Seasonal ARIMA models   Monte Carlo experiments

Links between the columns

It would not be realistic to assume that the 12 series corresponding to the months are non correlated.

The process (U_t) is not a WN in general: $Cov(U_t U_{t+h}) \neq 0$.

To account for these correlations, the process (U_t) is modeled by an ARMA(p, q):

$$\phi(B) U_t = \psi(B) \epsilon_t$$

where $\{\epsilon_t, \ t \in Z\}$ is a WN with variance σ^2.

Box-Jenkins methodology

Global model

Combining the different models - and differencing if necessary - we have

Definition:

A $\text{SARIMA}(p, d, q)(P, D, Q)_s$ process with period s is any process (X_t) such that

$$Y_t = (I - B)^d (I - B^s)^D X_t$$

is a causal ARMA:

$$\phi(B)\Phi(B^s)Y_t = \psi(B)\Psi(B^s)\epsilon_t + c$$

where ϕ, Φ, ψ, Ψ are polynomials of degrees p, P, q, Q respectively.

Box-Jenkins methodology
Integrated ARMA models
Seasonal ARIMA models

Definition of a SARIMA
Leisure employments in US
Monte Carlo experiments

Identifying a SARIMA from the autocorrelations

1. Search d **(0, 1 or 2)** and D **(0 or 1)** such that
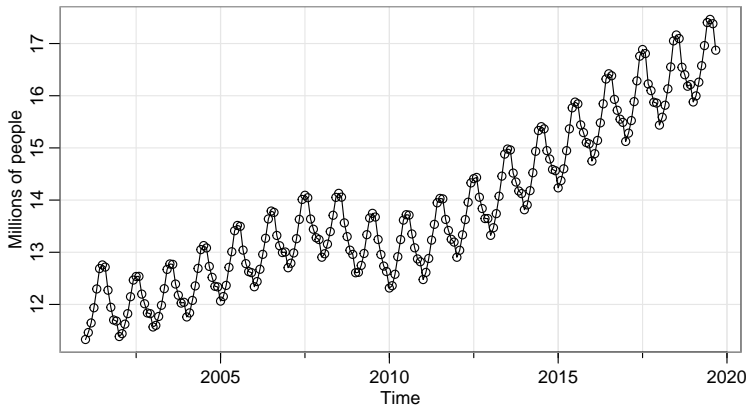

$$Y_t = (I - B)^d (I - B^s)^D X_t$$

   looks stationary.

2. Examine the empirical autocorrelations and partial autocorrelations of (Y_t) at lags multiple of s. Identify the orders P and Q.

3. Select the orders p and q by comparing $\hat{\rho}(1), \ldots, \hat{\rho}(s-1)$ to the autocorrelations of an ARMA(p, q)

4. For p, P, q, Q and d fixed, estimate ϕ, Φ, ψ, Ψ and σ^2 by LS. The series (Y_t) is an ARMA$(p + sP, q + sQ)$ with some coefficients equal to zero. The parameters are thus estimated by specifying the multiplicative relations of the model.

5. Use information criteria and validity checks to choose the most appropriate SARIMA models.

Ljung-Box test
data:  Residuals from ARIMA(1,1,2)(1,1,1)[12]
Q* = 3.0525, df = 5, p-value = 0.6919
Model df: 5.    Total lags used: 10
```

Box-Jenkins methodology
Integrated ARMA models
Seasonal ARIMA models
Definition of a SARIMA
Leisure employments in US
Monte Carlo experiments

Estimation of a SARIMA$(1,1,2)(1,1,1)_{12}$

The diagnostic tests are good

Residuals from ARIMA(1,1,2)(1,1,1)[12]

Box-Jenkins methodology
Integrated ARMA models
Seasonal ARIMA models
Definition of a SARIMA
Leisure employments in US
Monte Carlo experiments

Let us try a SARIMA$(1,1,2)(0,1,1)_{12}$

The diagnostic tests do not reject the model

Residuals from ARIMA(1,1,2)(0,1,1)[12]

Model comparison with information criteria
AIC and BIC select the SARIMA$(1,1,2)(1,1,1)_{12}$

```
>
> AIC(res111111$fit, res212111$fit, res112111$fit, res112011$fit)
          df      AIC
res111111$fit  5 2841.684
res212111$fit  7 2819.248
res112111$fit  6 2817.623
res112011$fit  5 2833.846
> BIC(res111111$fit, res212111$fit, res112111$fit, res112011$fit)
          df      BIC
res111111$fit  5 2866.158
res212111$fit  7 2853.511
res112111$fit  6 2846.991
res112011$fit  5 2858.319

Definition of a SARIMA
Leisure employments in US
Monte Carlo experiments

Forecasts from the estimated SARIMA$(1,1,2)(1,1,1)_{12}$ model

Forecasts from ARIMA(1,1,2)(1,1,1)[12]

Box-Jenkins methodology
Integrated ARMA models
Seasonal ARIMA models

Definition of a SARIMA
Leisure employments in US
Monte Carlo experiments

Almost the same results with the SARIMA$(1, 1, 2)(0, 1, 1)_{12}$ model

Forecasts from ARIMA(1,1,2)(0,1,1)[12]

Box-Jenkins methodology | Definition of a SARIMA
Integrated ARMA models | Leisure employments in US
Seasonal ARIMA models | Monte Carlo experiments

Estimated and simulated models

True model:

$$(1 - 0.2B)(1 - B)(1 - 0.4B^{12})(1 - B^{12})X_t$$
$$= (1 - 1.4B + 0.45B^2)(1 - 0.7B^{12})\epsilon_t$$

Estimated model:

$$(1 - \underset{(0.0956)}{0.3191}B)(1 - B)(1 - \underset{(0.0672)}{0.3825}B^{12})(1 - B^{12})X_t$$
$$= (1 - \underset{(0.0818)}{1.5429}B + \underset{(0.0779)}{0.5872}B^2)(1 - \underset{(0.0501)}{0.7295}B^{12})\epsilon_t$$

End of Chapter 3 ☺ !
